RE: LB1129 (State-Provided Contraceptives) (Oppose)

The Nebraska Catholic Conference advocates for the public policy interests of the Catholic Church and advances the Gospel of Life through engaging, educating, and empowering public officials, Catholic laity, and the general public.

The Conference opposes LB1129 for several reasons: : first, numerous studies from sources across the ideological spectrum illustrate that greater access to contraception does not *reduce* unintended pregnancies and abortion, but in fact tends to *increase* both; second, studies purporting to show that increased contraception availability decreases abortion are largely estimates and projections with little or no supporting empirical data¹; and third, some studies have concluded that a rise in contraceptive use has been a significant factor in the breakdown of marriage, which comes with a high social cost that falls disproportionately on the poor.²

Two studies by the Guttmacher Institute, which receives significant funding from Planned Parenthood, found that 48% of women with unintended pregnancies and more than half of women seeking abortions were using contraception in the month they became pregnant.³ In addition, numerous studies examining sexual behavior and STD transmission have demonstrated a greater willingness to engage in sexually risky behavior when a person believes the risk has been reduced through the use of contraception.⁴ Researchers in Spain examined patterns of contraceptive use and abortion from 1997-2007 and found that a 63% increase in the use of contraceptives during that time coincided with a 108% increase in the rate of elective abortions.⁵ In July 2009, results were published from a three-year program in the U.K., conducted at 54

sites, which sought to reduce teenage pregnancy through sex education and advice on access to family planning, beginning at ages 13-15. “No evidence was found that intervention was effective in delaying heterosexual experience or reducing pregnancies.”⁶ In fact, young women who took part in this family planning program were more likely than those in the control group to report they had been pregnant (16% vs. 6%) and to have had early heterosexual experience (58% vs. 33%).⁷

Finally, a study published in 2019 which analyzed whether oral contraceptives played a causal role in the rise of non-marital births in the United States during the twentieth century concluded that access to the pill significantly increased both non-marital births and demand for abortion, and that the effects are especially concentrated among less educated families and minority women.⁸

In conclusion, the hard data available shows that increased contraceptive access does not result in fewer unintended pregnancies or fewer abortions, but tends to increase both. The Conference respectfully urges your opposition to this bill.
